Department of Civil Engineering and Engineering Mechanics
Montana State University

INTRODUCTION

Throughout Montana and across the nation the insatiable demands for water become greater and greater each year. Even in a water-rich state like Montana, there are many areas where water shortages have become more and more frequent and prolonged in recent years. The needs of an expanding population, coupled with ever-increasing per capita use of water make it imperative that those agencies responsible for managing this vital resource have at their disposal every tool that will help them do the most efficient and effective job possible.

The Water Resources Division of the Montana Department of Natural Resources and Conservation (successor to the State Water Conservation Board and more recently the Montana Water Resources Board) has been a major factor in the development of water resources in Montana. A total of 181 projects (45 of them major) including storage dams, diversion works, canals and structures, located in 50 of the state's 56 counties, have been constructed in whole or in part by this Agency. At one time or another the Department has been directly or indirectly associated with 773 separate projects, and at present has direct interest in about 100 projects. Each project is a separate enterprise, paid for by local users, and ultimately (after construction costs are repaid) each will revert to local ownership. Most Department projects were constructed as single-purpose irrigation units.

Until the present time, the Department projects have enjoyed a high degree of autonomy, with the Department providing mainly advisory and engineering services. Day-to-day operations have been controlled by local boards of directors. The various projects are regulated according to their water rights through the District Courts of the State, but such regulation does not constitute management to achieve optimal or multiple-purpose benefits. With the present impetus toward water conservation, and with the mandate given the Department by the State Legislature (in 1967) to develop and administer a State Water Plan, it is evident that the Department is going to have to play a more active role in the day-to-day operation of its own projects, and must prepare for the day when it will have to supervise the operation of non-Department projects as well.

In 1970 a proposal was submitted, asking for matching funds (Section 101) to conduct research aimed at the development of a "reservoir operations model." The model would be a series of mathematical relationships programmed for solution on a digital computer. It would incorporate operating rules and guidelines for each of the reservoirs in a given drainage basin, together with

current and historic hydrologic information, and would provide instructions for regulating the major components of the Water Resources Division projects.

The original proposal was not funded; but in 1971 the Montana University Joint Water Resources Research Center made funds available under the Center's allotment program for a one-year first-phase or "pilot" study. After discussions with engineers of the Water Resources Division and the U.S. Soil Conservation Service, and because of the limited time and funding available, it was decided to limit the study to preliminary analyses of one single-purpose reservoir. Hyalite Reservoir on Hyalite Creek (or Middle Creek) in Gallatin County, Montana, was selected for study.

HYALITE RESERVOIR

Hyalite Reservoir was constructed by the State Water Conservation Board (predecessor of the Water Resources Division of the Department of Natural Resources and Conservation) as a U.S. Public Works Administration project. It was completed in 1951. Individual users and groups of users (all farmers except for the City of Bozeman) in the Gallatin Valley entered into contracts with the Board whereby the users reimburse the State for the State's share of the construction costs, and pay the operation and maintenance costs for the project. Each contract specifies a volume of water (in acre feet) to which the user is entitled each year. This water is available to him from the reservoir on call.

Appendix A shows a list of users, and the volumes of water for which they have contracted. A total of 7,795 acre feet per year has been contracted. The reservoir has a useful storage capacity of 8,030 acre feet (U.S. Geological Survey figure).

The users are organized into the Middle Creek Water Users Association,

governed by a Board of Directors elected annually. The present secretary of the Board, Mr. A. C. Manry, directs the operation and maintenance of the project.

GENERAL STRATEGY FOR STUDY

Generally, developing optimum operation rules for a reservoir consists of the following phases:

- (1) Collection and compilation of inflow data. If sufficient data are not available, devise a method to generate synthetic data.
- (2) Identify the various purposes for which the reservoir releases are being used and develop a common measure of effectiveness.
- (3) Devise optimization methods, which will optimize any given objective using the above inflows and subject to any restrictions imposed by the physical conditions of the reservoir like the size, discharge capacity, etc. and policy of the management like fixing priorities between the various users, etc.

STUDIES MADE IN CONNECTION WITH HYALITE RESERVOIR

Reservoir Inflows

In connection with specific studies for Hyalite reservoir, the first phase itself created some problems. There is a U.S.G.S. gaging station about 7 miles downstream from the reservoir on Hyalite Creek (USCS Station 06050000-MSU Data Bank Number 41H03291-Hyalite Creek at Hyalite Ranger Station near Bozeman). Records of flow at this station are available from 1935 to the present. However, the natural flows have been affected by the operation of the reservoir since 1951. The only data available with regard to the operation of the reservoir were the monthly contents of the reservoir as recorded by

the U.S.G.S. (USGS Station 06049500-MSU Data Bank Number 41H93290-Middle Creek Reservoir). With the help of this data, it was possible to reconstruct the natural flows at the gage site on a monthly basis since the construction of the reservoir by adding changes in reservoir contents to the flow volume recorded for that month at the gage. This reconstructed data was tested by a double mass analysis. The natural flows recorded at the Hyalite gage before construction of the reservoir (1935-1951) and the reconstructed natural flows (1951-1967) were compared with flows recorded during the same period in the West Gallatin River at Gallatin Gateway. The correlation between the flows was striking (see Figure 1 and Appendix B).

Another effort made was to synthesize data from the natural flows available from 1935-50. Using the statistics of the flows for these 16 years, the following model from the Harvard Water Program as published in "Design of Water Resources Systems," was adopted for generation of flows.

$$Q_{I+1,J+1} = \bar{Q}_{j+1} + b_j(Q_{i,j} - \bar{Q}_j) + t_j \sigma_{j+1} (1 - \gamma_j^2)^{1/2}$$

where $Q_{i,j}$ = flow generated for year i and month j

j = month

i = year

γ_j = correlation between natural flows for month j and month $j+1$

σ_j = standard deviation of natural flows for month j

$b_j = \gamma_j (\sigma_{j+1} / \sigma_j)$

As a trial 16 more years of flow were generated. Hydrographs of natural flow and synthesized flow are shown in Figure 2, for comparison. The line labelled "natural flows" was obtained from the average monthly flows which occurred for the 16 years 1935-1950 inclusive. The line labelled "synthesized flows" was obtained from the average monthly flows which were generated for 16 years by the synthesis technique. There seems to be striking agreement between the

FIGURE 1

Comparison of Hyalite Flows with
West Gallatin Flows (1935-1969)

Note: Hyalite flows 1951-1969 have
been adjusted for change in storage
at Middle Creek Reservoir.

FIGURE 2

Hydrographs of Natural and "Synthesized"
Flows at Hyalite Ranger Station

("Natural Flows" average of 16 years
1935-1950; "Synthesized Flows" average
of 16 years generated data)

two hydrographs, though the "generated" flows seem to indicate slightly higher peaks.

In further analyses reported herein, the flows as reconstructed from the double mass analysis with the Gallatin River are used. If future detailed analyses requiring several sequences of flows should be attempted, the procedure for synthesis of flows described above could be used.

While the double mass analysis described earlier established a reasonably good method for computing the natural flows at the gage site in spite of the reservoir, estimation of the amount of inflow into the reservoir presented more difficulties. Two branches of Hyalite Creek, viz, the West Fork and the East Fork, feed into the reservoir. While limited observations of flows (in the summer months of 1966-69) are available on West Fork, the flows in East Fork were measured in a Parshall flume only during the summer of 1969. The flows in the West Fork were subjected to double mass analysis with flows at the downstream gage and with flows in the West Gallatin River at Gallatin Gateway (Figure 3). From this analysis it appears that a fair estimate of the flows in the West Fork can be taken as 45% of the adjusted flow at the downstream gage.

Studies made by Phil Farnes (U.S. Soil Conservation Service) and by Michael Watson (MSU) indicate that the total inflow into the reservoir is about 64% of the adjusted flow at the downstream gage. Farnes used snow survey data in working out a water budget for the basin; Watson compared Hyalite flows with flows from Sourdough water shed (a similar basin adjacent to Hyalite on the east).

Using this proportion the inflows into the reservoir were estimated on a monthly basis.

A computer program was written for this phase of the work.

Appendix B shows the monthly inflows. Appendix C shows Snow Survey measurements.

Reservoir Uses

The reservoir is used by members of the Middle Creek Water Users Association. The primary use is irrigation, but the City of Bozeman has contracts for 2510 acre feet (nearly 1/3 of the reservoir capacity) for municipal water supply. There is some recreation use of the reservoir itself, particularly from residents of the City of Bozeman. Late summer flows in Hyalite Creek downstream from the reservoir are augmented by reservoir releases thereby enhancing fishing and other recreation use along the stream.

With proper reservoir regulation a limited amount of flood control may be possible downstream from the reservoir. The maximum discharge observed at Hyalite Creek at the Hyalite Ranger Station was 956 cfs (in 1898). Since construction of the reservoir in 1951 the discharge has reached 866 cfs once (in 1970) and 600 cfs twice (in 1959 and 1968). (Reference - USGS records.) The 1959, 1968 and 1970 flows apparently caused no flooding problems. Bozeman newspapers published during the high flow periods for each of the three years were searched for reference to flooding. The May 19, 1970 Bozeman Chronicle reported flooding elsewhere in the Gallatin Valley, and alluded to flood potential in the Hyalite drainage, but subsequent issues did not report any Hyalite flooding. The Gallatin County Tribune for December 26, 1968 reported flooding in Hyalite Canyon, but this was a result of ice jams and occurred at a time when flow at the Hyalite Ranger Station was only 20 cfs. (See newspaper accounts, Appendix D).

Reservoir Filling Operations

The objective of an irrigation reservoir operator with respect to reservoir filling is to achieve a full reservoir by the end of the snowmelt runoff period. The most common operations practice is to fill the reservoir with the first water melted in the spring. Any snowmelt in excess of that required for filling is then passed over the spillway. This practice has a two-fold disadvantage. First, the reservoir is often full before the peak snowmelt discharge occurs, and the peak must be passed undiminished over the spillway, perhaps to cause flooding downstream. (Presence of the reservoir can, under some circumstances, produce even higher peak flows downstream than would have occurred without the reservoir). Second, the peak flow may be great enough to endanger the spillway itself.

Snow survey measurements have been made in Montana since 1922. The snow course network has been greatly expanded and procedures have been improved and standardized by the U.S. Soil Conservation Service. Streamflow forecasts (based on multiple regression techniques) are made available by the SCS as of the 1st of March, 1st of April, and 1st of May each year. Using the streamflow forecasts, it should be possible to effect considerable flood mitigation in high runoff years. If it is evident on the 1st of March that the snowpack is well above normal, then the early snowmelt could be released, and high flows during the peak of the melt period could be stored.

Two snow course stations in the Hyalite drainage above Hyalite Reservoir have been operated since before construction of the reservoir. These are Hood Meadow and Devils Slide. Figure 4 shows the average water content in the snow at these two sites on the 1st of April and 1st of May each year, plotted against April-July and May-July adjusted streamflow volume measured at the Hyalite Ranger Station. Figure 4 shows fair agreement for most years between snow pack water content and streamflow volume. Figure 5 shows a plot

FIGURE 4

Comparison of April 1 Water Content (average of Devils Slide and Hood Meadow courses) with April-July Flow at Hyalite Ranger Station (adjusted for change in contents, Middle Creek Reservoir); and Comparison of May 1 Water Content with May-July Flows (1951-1971)

FIGURE 5

Comparison of Predicted vs. Actual
 April-July (1955-1971) and May-July
 (1960-1971) Flows at Hyalite Ranger
 Station (adjusted for change in
 contents Middle Creek Reservoir)
 (Predictions by Soil Conservation
 Service, USDA)

of April 1st forecasts of April-July streamflow volume vs. April-July actual flows, and May 1st forecasts of May-July streamflow volume vs. May-July actual flows. (All flows have been adjusted to reflect changes in Hyalite Reservoir storage). Figure 5 shows rather good agreement between predicted and actual flows.

Montana Snow Survey Supervisor Phil Farnes reports that other factors besides snow pack information may be used in the streamflow prediction formula; he also indicates that the formula used is revised frequently. The snow course network in the Hyalite drainage has been expanded considerably since 1951 and now includes 5 stations. Farnes declined to release the prediction formula currently in use for Hyalite.

Flood Mitigation by Reservoir Filling Management

The preceding information suggests a method whereby filling of Middle Creek Reservoir could be delayed until late spring, thereby reducing the snowmelt flood peak. The method proposed is based on the following assumptions:

1. Unless the April 1st streamflow forecast is exceedingly low, no reservoir filling is necessary before May 1. (April-July streamflow predictions 1955-1971 were never less than 25,000 acre feet and April-July adjusted streamflows for the same years were never less than 20,000 acre feet -- 2.5 times the capacity of the reservoir).
2. The reservoir is to be full by July 1 each year.
3. May-June predicted inflow to the reservoir is obtained from the May 1 streamflow forecasts by the following:

0.78[0.64 (May-July Streamflow Forecast)]

(See earlier discussion indicating reservoir inflow is about 64% of adjusted Hyalite Ranger Station flow; July inflow for years 1951-1971, expressed as a percentage of May-July inflow ranged from 12.4% to 30.4% with the average being 22.0%.)

4. Cumulative reservoir inflow after May 1 can be obtained from:

$\Sigma[0.64 \text{ (Hyalite Ranger Station Flow + Reservoir Gain - Reservoir Loss)}]$

Reservoir inflow yet to come (prior to July 1) is obtained by subtracting the cumulative reservoir inflow (assumption 4) from May-June predicted inflow (assumption 3). It should not be necessary to store any water in the reservoir until the "inflow yet to come" calculation drops to 8000 acre feet. At that point all inflow should be stored. The 36% of "Hyalite Ranger Station" flows originating below the reservoir should be adequate in most cases to meet downstream user demands during the storage period. In actuality of course, some reservoir release will be necessary to meet minimum flow requirements for fish, so the storage period will need to begin somewhat earlier (when the "inflow yet to come" drops to say 10,000 acre feet).

A further safety factor could be attained by allowing for possible inaccuracies in the streamflow forecasts. (See Figure 5).

OPTIMIZATION STUDIES

Actual optimization studies could not be conducted for Hyalite reservoir due to non-availability of actual data at that time. However, operation of a single reservoir like this should not present any real difficulties. Just to demonstrate the possible approaches to solving this problem two pilot studies

one using linear programming techniques and the other using dynamic programming, were made with hypothetical data. Following are brief descriptions of the two studies.

Linear Programming

Let us consider the operation of a single reservoir over a period of 4 seasons. This problem is solved using a canned package called MFORLP, available on Xerox Data Systems - Sigma 7 computer.

1. Mathematical Formulation

a. During Season 1

Let S_1 be the storage available at the beginning of season 1.

Let I_1 be the inflow during season 1.

Let R_1 be the release during season 1.

Let S_2 be the storage at the end of season 1 (and hence at the beginning of season 2).

Then continuity demands that

$$S_1 + I_1 = R_1 + S_2$$

b. Similarly for Season 2

$$S_2 + I_2 = R_2 + S_3 \quad \text{etc.}$$

In the problem considered here, S_1 is assumed to be 20 units (say thousands of acre feet). The inflow pattern during a four season cycle is assumed as follows:

Season	1	2	3	4
Inflow (1000 AF)	40	20	10	20

The objective of the operation policy is to maximize profits. The worth of water in various seasons is as given below:

Season	1	2	3	4
Value/Unit	2	10	9	3

The reservoir is assumed to have a maximum capacity of 100,000 AF. It is desired to have a storage of 20,000 AF at the end of season four.

2. Formulation in L.P.

From the above data, the L.P. problem can be formulated as follows:

a. Objective function

$$\text{Max. } Z = 2R_1 + 10R_2 + 9R_3 + 3R_4$$

Subject to the constraints:

$$\begin{array}{llll}
 1. & R_1 + S_2 & = I_1 + S_1 = 20 + 40 = 60 \\
 2. & -S_2 + R_2 + S_3 & = 20 \\
 3. & -S_3 + R_3 + S_4 & = 10 \\
 4. & -S_4 + R_4 + 20 & = 20 \\
 5. & S_2 & \leq 100 \\
 6. & S_3 & \leq 100 \\
 7. & S_4 & \leq 100 \\
 & s_i, R_i \quad (i = 1, 2, 3, 4, 5; \quad i = 1, 2, 3, 4) \geq 0.
 \end{array}$$

Computer coding and results may be seen in Appendix E. Discussion of the results of the computer program follow.

b. Interpretation of the Result

The primal solution is

$$Z_1^* \text{ (optimum) = Maximum Revenue = 890 units}$$

$$R_1^* = 0$$

$$R_2^* = 80$$

$$R_3^* = 10$$

$$R_4^* = 0$$

$$S_2^* = 60$$

$$S_3^* = 0$$

$$S_4^* = 0$$

(Slacks are not included)

It may be noted that maximum possible discharge is recommended in the second and third seasons when the revenue is maximum. The recommended discharge in first season (R_1) is zero, thus conserving water for discharge during the second season, when it brings more revenue.

The Dual

The Dual solution is

$$Z_2^* \text{ (optimum) = minimum cost = 890 units}$$

$$Y_1^* = 10$$

$$Y_2^* = 10$$

$$Y_3^* = 9$$

$$Y_4^* = 3$$

$$Y_5^* = 0$$

$$Y_6^* = 0$$

$$Y_7^* = 0$$

(slacks are not included)

The inflows during first, second, third and fourth seasons, have imputed values of 10, 10, 9 and 3 units, respectively. This is obvious as increase of inflows during these seasons will help greater releases R_2 , R_3 and R_4 , bringing revenue of respectively 10, 9 and 3 units respectively. However in real life situations, increasing the inflows is not possible, as they are a result of natural phenomena. Even the assumption of prior knowledge of these inflows is not realistic, as it is usually not possible to know definitely, future inflow pattern.

Dynamic Programming

Let us assume that we have a reservoir which is being used for (1) recreation and (2) flood control. Let us further assume that we can establish the loss in either use associated with any policy, as shown in Figures 6(b) and 6(c). Also, let us assume that we know the inflow for five consecutive seasons: $x(1) = 4$, $x(2) = 1$, $x(3) = 3$, $x(4) = 0$, $x(5) = 4$. Let us consider three states of storage: full (2); half-full (1); and empty (0).

Solution:

Stages = seasons (I) $1 \rightarrow 5$

States = Storage (S) $0 \rightarrow 2$

Decision Variables = Discharge (D) $0 \rightarrow 2$

Procedure:

- 1) At any stage the starting storage can be $0 \rightarrow 2$, and by any policy we can reach any of the states $0 \rightarrow 2$. (Of course, the limitations are: (i) the beginning storage (K) cannot be more than ending storage (J) - inflow in the season (X(I)), and (ii) the ending storage (J) cannot be more than beginning storage (K) + inflow in the season (X(I)) and both cannot be more than the full storage (2) or less than no storage (0)).
- 2) The loss (L) associated with our policy in any season (I)
$$L = (\text{Loss due to Recreation } LR(J) + \text{Loss due to flood } (LF(K + x(I) - J))$$

in the season + minimum loss due to our policy up to reaching the stage (LMEM(I - 1, K)).
- 3) As we can start at any state (K) to reach the present state (J), we would like to choose only that state (K*) which minimizes the overall loss, and store this value of K* for later reference.
- 4) Proceed to calculate the minimum Loss (LMEM) and trace back state (SMEM) associated with each state (J) at each stage (I), until the last stage (Season 5 in this case), is reached.
- 5) Then select the state which has the overall minimum loss (MINL).
- 6) Starting from this point trace back to determine the policy. Please see detailed working in Figure 6.

Computer coding and output may be seen in Appendix F.

a.

— Optimal Path

FIGURE 6 Dynamic Programming Example

Other Studies

In connection with another study, an approach to solve reservoir operation problem via simulation in GASP language was attempted. Of course, this simulation approach does not necessarily lead to an optimal solution, but its potentiality for use in reservoir operation situations was demonstrated. This is particularly worth considering in case it is intended to use stochastic inflows.

Several useful references using these techniques have been mentioned in the bibliography of reference 2.

CONCLUSIONS

The study began as a pilot project for a larger investigation involving integrated operation of systems of reservoirs in Montana. The Mussellshell Basin has been chosen for such a study and at present a much more extensive study is underway. The studies described herein formed the groundwork for this larger study, (B-038 MONT).

APPENDIX D

Newspaper Accounts of Hyalite Flooding

THE GALLATIN COUNTY TRIBUNE

And Belgrade Journal

Vol. No. XIX 3 Bozeman, Montana, Thursday, December 26, 1968

Outdoor Enthusiasts Stopped by Flood

Hyalite Canyon Road presents a formidable picture as Montie Stanhope and David Thomas, of the Gallatin County Tribune, work their way out of the canyon Sunday

afternoon. It took them a little over three hours of shoveling ice, removing tree stumps and debris to get their vehicles down the road.

They were assisted by other persons (see photo) who wielded their axes in an effort to remove the trees. Middle Creek can be seen to the right of the

Tribune Photo By Montie Stanhope

picture. The ice and water on the road was pushed by such pressure that it extended great distances at a number of points down the canyon on the road.

Anyone touring the Hyalite Canyon Sunday was in for a surprise when they returned home that afternoon. The canyon road had become, of all things, flooded by Middle Creek. Ice dams had been formed in the Creek by

blocks of ice catching on logs and forming dams. This caused the water to wash over the road, thereby picking up more ice and debris and causing flooding further down the creek. After the water pushed

the ice and debris ahead of it the road remained relatively clear. Sheriff L.D.W. Anderson, who was called to the scene, called Forest Service personnel to the area. "We wanted to make certain no one was trapped

in the canyon," said Ross MacPherson, Bozeman district ranger, "There were 20 to 30 cars above the debris." In one area of the Hyalite road water was backed up about a

Officials Plan Schools

Christmas Shopping?

Nativity Scene Re-Created

The Security Bank and Trust Company of Bozeman has depicted an unusual nativity scene for local spectators. The theme of the scene is the birth of Jesus.

Losses have been listed as occurring from the following: loss due to selling hay at a discount; losses on cattle that they were forced to sell and then the

contribution to Christmas that brings smiles to the faces of passersby and highlights their day.

extra cost of bringing out-of-state cattle to replenish their herds; trucking expenses on this item; losses incurred because they had to borrow money and pay

Tribune Photo by Donna Brown

During the holiday season, Christmas through New Years, Sheriff L.D. W. Anderson, Sgt. of the Highway Patrol, Buck Baldry and Chief of Police Ron Cutting, urge all the public to drive in a safe and prudent manner.

Above all, they urge, be careful of excessive use of intoxicating beverages throughout the holiday season.

interest on it while under restraint; losses incurred by boarding unproductive cows for a long period of time; losses incurred by having to pay for the testing of their hay.

Indemnities Paid

At the present time, only indemnities for milk produced and destroyed can be paid.

The ASCS office has received applications from three milk producers in three other counties, Fergus, Cascade and Lake, asking for indemnities.

These dairies were not restrained from selling milk but their processors refused to buy their milk because of pesticide content.

Indemnities totaling \$43,716 were paid out to 26 dairymen earlier.

Officials Urge Public To Use Care

All law enforcement agencies plan to be out in force to apprehend those who fail to obey the law. The cooperation of the public will be appreciated.

As a reminder to those who may receive firearms, the sheriff's office said it is unlawful to discharge firearms

within three miles of the city limits.

The Sheriff's office also asks that those who have snowmobiles should remember they are not to travel any public streets, county roads or highways.

"Be courteous and obey the law. We wish a merry Christmas and a happy new year to everyone," says the Sheriff's office.

Officers Elected To Lodge No. 18

At the regular meeting of Bozeman Lodge No. 18, on Thursday, December 5, 1968, officers for the year 1969 were elected.

Elected were: Robert M. Holter, Worshipful Master; Raymond K. Shackelford, Senior Warden; James L. Simpson, Junior Warden; Kenneth E. Monroe, Secretary; William Holmes, Treasurer; Leslie E. House, Trustee.

Installation in conjunction with Gallatin Lodge #6 was held at 7:30 p.m., Thursday, December 19 at the Bozeman Lodge #18 Hall.

Preceding the installation, a free pancake supper was served at 6:30 p.m. for all Masons.

Flood:

(continued from front page)

quarter of a mile.

This happened when a large tree fell into the creek and wedged behind a bridge causing the ice and water to back up.

"This is the first time Middle Creek has done this in four or five years," said MacPherson. "The last time it happened we had to use dynamite to break up a jam."

The road was closed the early part of the week to vehicles other than pickups or four-wheel drives.

The Three D Lumber company worked plowing the roads clear while the Forest Service cleared logs from under the bridges so this back-up wouldn't happen again.

Bozeman—Considerable cloudiness through Wednesday with showers and thunderstorms mostly during afternoons and evenings. Shower activity decreasing on Wednesday. Low tonight 39, high Wednesday 58.

BOZEMAN DAILY CHRONICLE

BOZEMAN, MONTANA, TUESDAY EVENING, MAY 19, 1970

10c

Gallatin Valley Flooding Potential 'Critical' Now

By ANNABELLE PHILLIPS
Chronicle Staff Writer

The flooding potential in the Gallatin Valley is already critical and the weatherman holds the key to the future.

Currently, low elevation streams are raging out of their banks. And, at the present snowmelt rate, they will not reach their peak flow for about another two weeks.

The major streams — West Gallatin, Madison, Jefferson and Missouri — are high but, as yet, are causing no trouble. Peaking point for the waters of these rivers should be around mid-June.

The weather, however, can bring about a dramatic change.

A few days of high temperatures or rain, or a combination of the two, will bring about a rapid increase in all streamflows. Should this happen, most of the streams and rivers will be out of their banks.

The mountain snow pack this year is abnormally large, particularly at lower elevations. At many of the high elevation sites there was more than 100 inches of snow on May 15, Phil Farnes, snow survey supervisor for the Soil Conservation Service, said today.

Take the Hyalite Drainage, for instance. At Shower Falls, where the elevation is 8,100, there was 105 inches of snow and the water content was 45.2 inches. Snow depth at this point last year was 43 inches and water content 21.3 inches. The average water content for the period of 1953 to 1967 was 28.5 inches.

At Devils Slide, which also has an elevation of 8,100, the snow depth was 92 inches on May 15 and the water content 39 inches compared to a 21 inch snow depth and 8.6 inch water content a year ago.

At Lick Creek, 6,860 elevation, there was 50 inches of snow with a 17.2 water content. Last

year on the same date there was no snow in this area.

There was 43 inches of snow at Hood Meadow, 6,600 elevation, and the water content was 17.2. Last year there was an inch of snow on May 15.

The Bridger Creek snow course paints about the same picture as far as the snow goes.

Bridger Bowl, with an elevation of 7,250, had 103 inches of snow and the water content

was 43.4 inches. Last year there was 33 inches of snow with an 18.1 water content. The 1953-67 average water content was 27.6.

(See Flooding, Page 3)

Regents Stay Mum On MSU President

HELENA (AP) — One of three men has been chosen as president of Montana State University but the State Board of Regents is keeping the new president's name secret.

A source said the name would not be released until later this week after such details as when the new president can take over have been determined.

The board reached its decision during a meeting in Helena Monday. The Associated Press learned the new president of the 7,700-student school will be one of three men interviewed by the board this month.

They are: — Carl W. McIntosh, president of California's Long Beach State College, which has more than 24,000 students and about 1,300

teachers, he was interviewed on May 1.

— Roy E. Huffman, Bozeman, MSU's vice president for research and director of its Endowment and Research Foundation. He was interviewed Sunday.

— Dean Stebbins, academic vice president of Michigan Technological University, Houghton, who was interviewed Monday.

Another candidate, who had been recommended by a special screening committee of the Board of Regents, withdrew his name from further consideration. He was Duane Ackre, dean of agriculture at South Dakota State University.

Since the death of MSU President Leon H. Johnson last June 18, Regents of the Montana Uni-

versity System have been looking for top candidates.

The school, second largest of the system's six units, has been operating under the direction of Acting President William A. Johnstone.

Johnstone, however, withdrew his name from consideration and is expected to return to his former position as administrative vice president when the new president takes over.

The announcement is expected within a day or two from the office of the system's executive secretary, Edward W. Nelson.

One source said the reason for the delay in announcing the name of the new president is to provide time to determine a number of details, such as the starting date.

Reds Step Up Attacks in South Vietnam

SAIGON (AP) — North Vietnamese and Viet Cong troops stepped up their attacks across South Vietnam sharply today in a new "highpoint" of activity apparently marking the 80th anniversary of the birth of Ho Chi Minh.

The Communist command's troops also threatened another Cambodian provincial capital in their efforts to keep open their supply lines through northern Cambodia and southern Laos.

World News Briefs

By THE ASSOCIATED PRESS

Eighteen days after President Nixon sent American combat troops into Cambodia, student protest strikes were under way at a reported 265 colleges. However, the disorders and scattered violence which characterized the first two weeks of protest have subsided.

WASHINGTON (AP) — All nine Negro members of the House, charging the White House with "obstructionism,"

WASHINGTON (AP) — The old tactic of "manufacturing" wars and crises into line, ridiculed and discredited by the Nixon administration, seems to be making a comeback.

Carefully choosing their words, Federal Reserve Chairman Arthur F. Burns and Housing Secretary George F. Moore, both indicated Monday the new approach would be used to

High temperatures resulted in the flood over the road and into the low-lying to the west, receding about 3 - 4 inches.
